CHOSEN

THE HIDDEN QUESTION WE SPEND OUR LIVES ANSWERING

JAMIE ANSON

PEER REVIEW MANUSCRIPT · SEPTEMBER 2026

PART I

THE QUESTION

Three hundred thousand years ago, there were humans. Not something vaguely human. Not monkeys waiting to become us. Us. Homo sapiens. Our species has been around for roughly 300,000 years.

Imagine being one of them. You don't have a job. You don't have money. You don't have a country, a credit score, a mortgage or a retirement account. There is no grocery store, hospital, police department or university. No Instagram. No Google. No Uber Eats. Nobody is asking you to reset your password because it needs one capital letter, two numbers and a fucking hieroglyphic.

There are people. That's basically your world.

The people around you know where the water is. They know which plants will feed you and which ones will kill you. They know how to make tools, find animals, protect children, carry the injured and survive a winter. If those people stop wanting you around, there is no apartment across town and no LinkedIn post announcing that you are excited to explore new opportunities. For an enormous part of human history, other humans weren't merely one pleasant part of life. They were part of the infrastructure keeping you alive.

Then humans did something extraordinary. We built more infrastructure. Agriculture. Cities. Writing. Money. Kingdoms. Hospitals. Corporations. Governments. Universities. Insurance. Airplanes. Refrigerators. Therapy. Tinder. Excel. The human animal did not disappear. We gave it pants. We put it inside an office tower and gave it Microsoft Excel. And then we became extremely confident that we understood it.

WE ARE EARLY

In 1949, António Egas Moniz received half of the Nobel Prize in Medicine for helping develop an operation called a leucotomy. If you have no idea what that means, good. The word makes it sound cleaner than it was. Doctors deliberately cut connections in the front part of a person's brain in an attempt to change severe mental symptoms.

1949. Not 1499. We had airplanes, radio, antibiotics and nuclear physics. Einstein was alive. These were not people living in caves. They had universities, journals, experts, conferences and credentials. They believed they were practicing modern science.

Walter Freeman later popularized a faster American version in which an instrument shaped like an ice pick could be passed through the thin bone above the eye and into the front of the brain. Some patients were reported as improved. Others were left with seizures, disability, major personality changes or death.

The lesson is not that every doctor involved was cruel. Many were trying to help people for whom there were few effective treatments. That almost makes the lesson worse. Smart, educated, well-intentioned humans can do something grotesque while sincerely believing they are the advanced ones. Every generation has a dangerous little fantasy: We finally know what the fuck is going on. Then the next generation arrives.

That does not make modern psychology, neuroscience or economics equivalent to lobotomy. It means they are unfinished, because every science is unfinished. Somebody noticed attachment. Somebody noticed loss aversion. Somebody noticed conformity, rejection, psychological safety and relational uncertainty. Somebody saw a pattern, found a way to measure it, and invited other people to try to break it.

I think there may be another pattern worth measuring. Not a replacement for the others. Not a theory that explains everything. Two numbers that may be hiding in plain sight.

The first is value: how much would losing this particular relationship or group matter to me? The second is security: how likely do I currently believe it is that I will still belong here tomorrow?

Here, membership does not mean enrollment. It means an expected continued place in a particular relational world: this family, friendship, marriage, team, workplace, community or group. And security, S, is deliberately narrow. It is the person's estimate that this defined place will continue across a defined period or event. It is not automatically the same thing as status, job security, emotional responsiveness, psychological safety or moral worth, even though those things can affect the estimate.

The second word matters: believe. I do not need to be about to lose you. I need to think I might. Human beings cannot directly inspect another person's future intentions. We estimate. A delayed text, an invitation, a laugh, a criticism, a promotion, a new friend, a hand on a shoulder, a closed bedroom door. Tiny events become evidence.

Maybe that is why the same event can feel completely different to two people. If I believe my place with you is safe, a disagreement can remain a disagreement. If I believe my place is fragile, the same disagreement can feel like the first step toward exile.

In ordinary English, the whole book keeps asking two questions.

Do you choose me?

Do you still choose me?

Psychology already knows belonging matters. That is not the claim. Researchers have spent decades studying attachment, acceptance, rejection, conformity, relationship uncertainty, identity, commitment and psychological safety. Good. The question here is narrower: can we separately measure how much a particular membership matters and how secure that membership currently feels? Then, when something happens, can we measure how much

that security estimate changes? And does knowing those things help predict what the person does next?

Maybe. Maybe not. If the answer is no, throw the idea away. A mathematical model can tell us what follows from its assumptions. It cannot prove that the assumptions describe eight billion human beings. If an existing theory already predicts the behavior just as well, use it. If these two numbers cannot be measured separately, drop them. If they add nothing, let them die. Better a dead idea than a protected one.

THE ANSWER I HAD NO REASON TO TRUST

On December 29, I ate 0.99 grams of fresh Golden Teacher mushroom. I am telling you this near the beginning because hiding it until the end would be a cheap trick. The first version of this idea did not arrive from a spreadsheet. It arrived while I was under the influence of psilocybin.

My life was difficult. Relationships, business and family were consuming enormous amounts of attention. I was drinking more. Using THC more. Scrolling more. I felt nauseated and sat staring at my laptop. Then a thought arrived with embarrassing simplicity: close the laptop. The answer is in the real world.

I did. The room remained the same room, but my experience of it changed. Everything felt warm, connected and safe. I thought about my dog, my parents, my children, pride, care and belonging. The word that appeared was love. Then my brain did what it always does. It tried to turn a feeling into a model.

Love plus one. Fear minus one. Two liquids in a cup. Pour in love and fear gets displaced. But I could not simply order my own cup to fill. In the picture in my head, I had to pour into other people and trust that love could move through the system. It was ridiculous. It was also one of the clearest experiences of my life.

An hour later the acute effects faded. The question did not. Was it psilocybin? Obviously. Was it also memory, exhaustion, expectation and everything else happening in my life? Almost certainly. Was it God? I have no instrument that can answer that.

More important, I had just been handed an answer I had absolutely no reason to trust. The experience proved nothing. It gave me a question. Altered states can generate vivid connections; vivid is not the same thing as true. If the question was useful, it should survive contact with everything humans had already learned. If it was bullshit, I wanted to find the wall. So I started looking for places it should break.

PART II

WHAT WILL YOU DO TO REMAIN ONE OF US?

ONE IN NINE

Vienna in the 1840s had a problem that should have been impossible to ignore. The General Hospital ran two maternity clinics. In 1846, 4,010 women gave birth in the First Clinic and 459 died. That is 11.4 percent. In the Second Clinic, where midwives were trained, 105 of 3,754 women died, about 2.8 percent. The difference was not hidden in some statistical fog. Women knew. Some begged not to be admitted to the First Clinic. A woman could arrive at a hospital looking for help and discover that the identity of the people assigned to help her changed her odds of leaving alive.

Ignaz Semmelweis was a young Hungarian doctor working in the First Clinic. He chased explanation after explanation. The position women gave birth in. The priest who walked through the ward. Crowding. Air. Fear. None of it satisfactorily explained why one clinic was so much deadlier than the other. Then a colleague, Jakob Kolletschka, died after being cut during an autopsy. The illness looked horribly familiar. Semmelweis began to suspect that doctors and medical students were carrying something from corpses to living women on their hands. Germ theory was not yet available to him as the clean explanation we inherit today. He called the suspected material cadaverous particles.

He ordered doctors and students to wash their hands in a chlorine solution before examining women. In 1848, after the washing rule had been used consistently, 45 of 3,556 women in the First Clinic died. About 1.3 percent. The clinic that had killed roughly one woman in nine in 1846 was now killing roughly one in eighty. The numbers did not require a microscope. Something enormous had changed.

The familiar version of this story is comforting because it has a hero and idiots. Semmelweis discovers handwashing. Arrogant doctors refuse to listen. Science eventually wins. Real history is messier. Semmelweis did not have modern germ theory. His explanation was incomplete. Medical theories of disease were different. His communication became combative. Some contemporaries did accept parts of his practice. The point is not that every doctor who resisted him was stupid or evil. The point is more uncomfortable: evidence can arrive before a group has a safe way to absorb what the evidence means. History becomes stupid when we turn everybody who disagreed with the eventual winner into a cartoon villain.

Imagine what acceptance demanded. It did not merely say, Here is a better soap. It implied that the hands of physicians, the people trained to heal, had helped carry death from autopsy rooms to mothers. A factual update could also be an identity wound. That does not prove belonging caused the resistance. It gives us a question worth carrying through the rest of this book: what happens when changing your mind changes what your membership, competence, status, or moral identity means? Evidence may be free. Believing it can be expensive. What makes being wrong more expensive than staying wrong? Dead ideas are cheaper than dead mothers.

THE LINE IS OBVIOUS

Solomon Asch had a problem with an earlier kind of conformity experiment. If you put people in a dark room and ask them to judge how far a tiny point of light moved, there is no obvious answer. People influence one another partly because the world itself is ambiguous. Asch wanted to remove that excuse. He wanted a situation where a person could look directly at reality and know the answer.

So he used lines. One card showed a single line. Another showed three comparison lines. One was obviously the same length as the first. The task was so easy that people working alone almost never got it wrong. Then Asch put a real participant in a room with a group of men who were secretly working for the experimenter. One by one, the group members gave their answers aloud. On ordinary trials they answered correctly. Then came a critical trial, and every one of them calmly chose the same obviously wrong line.

Now imagine the timing. You have eyes. The answer is right there. The first man says the wrong thing. Strange. The second says it too. Then the third. The fourth. The fifth. Nobody is laughing. Nobody looks confused. By the time the answer reaches you, the experiment has changed. It is no longer merely a vision test. There are now two pieces of evidence in front of you. The card says one thing. Every other human in the room says another.

Across Asch's 123 participants, the wrong majority pulled responses toward it on 36.8 percent of the critical trials. That number is often mangled into the claim that 37 percent of people were conformists. It was 36.8 percent of critical responses. About a quarter of the participants never yielded at all. On most judgments, most people still said what they saw. The experiment is interesting because humans were neither sheep nor perfectly independent. They moved.

The interviews afterward make the movement more human. Some people who yielded came to doubt their own perception. Others believed the group was wrong but did not want to stand apart from it. Others tried to explain the discrepancy away. That distinction matters. A person can say the same wrong answer for very different reasons. One mind changes its belief. Another keeps the belief and changes the public behavior.

The standard explanation is social influence, and it is a good one. We do not need to rename Asch. The useful question is narrower: does the cost of standing alone change when the person believes disagreement could cost them a valued place? If disagreement is guaranteed to have no social consequence, does conformity fall? If dissent threatens exclusion from a group the person deeply values, does it rise? Now the idea can be separated from the original effect.

The line was obvious. That was Asch's genius. He stripped away uncertainty about the object and left uncertainty about the people. Our later experiments can ask whether the price of standing alone changes when continued membership is secure.

THE BORING GROUP

Initiation rituals are weird because the stated task often has almost nothing to do with the group. Eat this disgusting thing. Stay awake. Run until you vomit. Memorize nonsense. Wear the humiliating outfit. Let older members insult you. Pay the fee. Prove you want it. From the outside, the ritual can look like a tax on joining.

Psychology has several ways to explain why difficult initiation can increase attachment. One is effort justification. If I suffer to obtain something, admitting that the thing is worthless makes the suffering harder to explain. So the mind may raise the value of the prize. That idea sits comfortably inside cognitive dissonance theory and does not require CHOSEN.

But initiation also changes the social meaning of membership. A group that is difficult to enter can signal that membership is scarce, that other members paid a similar cost, and that leaving would abandon an investment. The ritual creates a story: people like us went through this. You are one of us because you did too.

The danger is obvious. If pain becomes evidence of loyalty, cruelty can masquerade as culture. Hazing survives partly because every generation can point backward. I endured it. Therefore it mattered. Therefore you should endure it. The suffering becomes part of the membership credential.

Suffering does not automatically make belonging secure. Sometimes the opposite happens. Abuse can make membership feel conditional on continued submission. A person may cling harder while feeling less secure. Value and security can move in different directions. That is exactly why separating the two variables matters.

A group can become extremely valuable while membership feels extremely fragile. That combination may be combustible. If I have sacrificed friendships, money, sleep, reputation and dignity to join, the group is now expensive to lose. If I also believe one wrong move can get me expelled, the social stakes of obedience become enormous. That high-value, low-security combination is one of the cases the concentrated experiments near the end of this book should test.

The most dangerous group may not be the one that makes you suffer to enter. It may be the one that makes you suffer to enter and then spends the rest of your membership reminding you that you can still be thrown out.

PART III

WHEN INFORMATION GETS EXPENSIVE

THE FINE

The daycare experiment in Haifa is useful precisely because nobody needs a theory of civilization to understand it. Parents were supposed to collect their children by closing time. Some arrived late, which meant a teacher had to stay. So six daycare centers introduced a fine. Ten Israeli shekels if a parent arrived more than ten minutes late. Four other centers served as comparisons. If price is punishment, the prediction seems obvious. Make lateness more expensive and get less lateness. The researchers called the paper A Fine Is a Price. The title contains the whole grenade.

They got more. Late pickups increased significantly after the fine appeared. Then the researchers removed the fine. Lateness did not simply snap back to its old level. Something about the meaning of the interaction had changed.

Money works. The interesting part is what the money changed besides price. The researchers argued that penalties enter relationships that already contain unwritten expectations. Before the fine, being late could mean making another person wait for you. After the fine, a parent could interpret the same act as a service with a price. Ten shekels changed information about what kind of situation this was.

Human beings do not respond only to the physical event. They respond to what the event means inside a relationship. If I am ten minutes late to meet a stranger, a friend, my child, a judge, and a person I desperately want to impress, the clock records the same ten minutes. My brain does not. Context changes the social prediction. This matters far beyond daycare. Every rule teaches people what kind of relationship they are in. Every incentive says something about what counts. Pay children for every book and you may teach them what reading is for. Measure employees only by a metric and you may teach them what the company actually values. Charge for behavior that used to violate a social norm and you may accidentally put it on the menu. We keep trying to change human behavior by changing the price. Sometimes the price was never the thing controlling the behavior.

But this experiment is also a warning for us. It does not prove belonging was the hidden variable. Social norms, guilt, pricing, expectations and incomplete contracts already explain a great deal. Merely pointing at a weird result and yelling belonging is not a theory.

THE PERSON WHO SAYS NO

Amy Edmondson became interested in a puzzle inside hospital teams. You might expect the best teams to make the fewest mistakes. In early work, she encountered something stranger: some teams that looked better also reported more errors. One possibility was horrifying. Maybe the better teams were not making more mistakes. Maybe they were better at admitting them.

That insight developed into the idea of psychological safety, which Edmondson defined as a shared belief that a team is safe for interpersonal risk taking. In a 1999 study of 51 work teams, psychological safety was associated with learning behavior. The phrase has since become corporate wallpaper, which is what happens to a useful idea after enough PowerPoint decks.

Strip away the jargon and the mechanism is brutal. If telling the truth can cost me status, respect, promotion or membership, I have two problems instead of one. I have the actual problem, and I have the problem created by revealing it.

A nurse notices a medication error. An engineer sees a defect. A junior analyst finds a hole in the forecast. A child knows Dad is wrong. A friend thinks the wedding is a mistake. The information exists. The question is whether the social system can receive it.

This is where secure belonging and psychological safety overlap, and the overlap has to be acknowledged rather than marketed as novelty. Edmondson already gave organizational science a way to think about interpersonal risk. CHOSEN's narrower addition is to ask whether the person's estimate of continued membership is one component of that risk, and whether measuring it improves prediction.

Those are not the same claim. I can fear humiliation without fearing expulsion. I can feel secure in my job but afraid of looking stupid. I can feel socially loved and still worry about losing authority. Status, competence and membership are related but separable.

So build the experiment to separate them. Tell participants that their place on the team is guaranteed, but that dissent may lower their status ranking. Tell another group that status is unaffected, but repeated dissent may cost future team membership. Give both groups the same hidden information and the same financial incentives. Which threat suppresses speaking up more?

If status wins, write status. If membership wins, write membership. If both matter, estimate both. The point is not to make every person who says no into a hero. The person may be wrong. The point is to build rooms where being wrong and being disagreeable are not confused with being disposable.

THE TRUTH THAT DIDN'T SURVIVE THE TRIP

Hierarchy is not the enemy. Airplanes, hospitals, armies and companies need roles. The problem begins when truth has to compete with belonging, status or future opportunity. If telling you what I see threatens my place with you, you have built a system with an incentive to become blind.

That is exactly why the case matters. Organizations rarely destroy information by placing it in a shredder. They change its social cost. A concern has to travel from the person who sees it to the person who can act on it. At every step, somebody has to decide whether speaking again is worth being difficult, slowing the schedule, challenging a superior, contradicting a customer, or becoming the person everyone wishes would shut up.

Every layer can edit reality without anyone consciously deciding to lie. A technician softens a sentence. A manager removes uncertainty. A vice president asks for stronger evidence. A room interprets silence as agreement. Then the person with the most authority can become the person with the least access to unfiltered reality.

On the night before Challenger launched, engineers at Morton Thiokol were worried about rubber seals called O-rings in the shuttle's solid rocket boosters. The forecast was unusually cold. During a teleconference, Thiokol engineers presented concerns about how the seals performed at low temperatures. The engineering recommendation was not to launch below 53 degrees Fahrenheit. The next morning was far colder than that.

The recommendation did not survive the organization. After discussion and a management caucus, Thiokol reversed its position and recommended launch. Challenger lifted off on January 28, 1986. Seventy-three seconds later the vehicle broke apart. Seven people died.

The official investigation also found that some of the people making the final launch decision did not know the full recent history of O-ring trouble. They did not know that Thiokol had initially recommended against launch, or how strongly some engineers still objected after management changed the recommendation. The truth existed. It just did not survive the trip.

It is tempting to turn the story into a morality play about cowardly managers silencing brilliant engineers. The Rogers Commission record is more complicated. The data were incomplete. People interpreted the evidence differently. NASA and contractor processes had normalized concerns over time. Communication moved through layers. Pressure existed without requiring a villain to announce, I would like to kill astronauts today.

PULL THIS CORD

In 1984, General Motors and Toyota reopened a car plant in Fremont, California, as a joint venture called NUMMI. The old GM plant had become notorious for terrible labor relations and terrible cars. More than 85 percent of the new NUMMI workforce had worked in the old plant. Toyota did not solve the problem by finding a different species of American worker. It changed the system around many of the same people.

One of the most visible changes was a thin cord hanging along the assembly line. The andon cord. In Toyota's system, a worker who saw a problem could pull it. The first pull summoned help. If the problem could not be fixed before the car reached a certain point, the line stopped.

That sounds like a manufacturing detail until you understand what an assembly line represents. A stopped line is visible. Expensive. Everybody knows where the interruption happened. In a system built around keeping production moving at all costs, admitting a problem can make the person who noticed it look like the problem.

This American Life's reporting on NUMMI captured workers describing how different this felt. At the old plant, defects could roll onward and be repaired later. Under the Toyota system, workers were expected to expose the defect now. Rick Madrid described watching a bolt problem get addressed during training in Japan and realizing that fixing it immediately simply made sense. One bolt changed his attitude.

The cord did not create courage through motivational posters. It changed the rules surrounding bad news. Pulling the cord was not sabotage. It was the job. The system tried to make discovery of an error valuable before the error became expensive.

This is a concrete version of the principle hiding underneath the Challenger story. Information does not travel merely because somebody possesses it. Institutions create prices for transmission. The price can be time, embarrassment, rank, career opportunity, conflict, or membership.

NUMMI is not a clean experiment proving secure belonging. Toyota changed many things at once: training, teamwork, job classifications, quality processes, labor-management relations and production methods. We cannot point to the cord and claim causality for the entire turnaround.

But the cord gives us a design question. What would the social equivalent look like? Not a literal rope in every marriage and boardroom. A rule that says: finding the problem early earns protection, not exile. The person who interrupts the process remains one of us.

The strongest version is not speak up. Every company already says that. The strongest version is to make the response to bad news observable. The first person who pulls the cord teaches everybody else whether the cord is real.

Culture is what happens to the second person after everyone watches what happened to the first.

THE WALLET WITH MORE MONEY

In 2019, researchers carried more than 17,000 wallets into institutions in 355 cities across forty countries. Some contained no money; others contained money. In virtually every country, wallets containing more money were more likely to be reported. More money increased the material reward for dishonesty, yet honesty increased.

The researchers did not conclude that belonging had defeated utility. Their evidence pointed instead to concern for the owner and the growing psychological cost of seeing oneself as a thief. Put more money in the wallet and stealing becomes more profitable, but it may also become harder to tell yourself that you are not really stealing. Humans carry reputations in other people's heads, and in their own.

That is why the wallet belongs here. It is not clean evidence for CHOSEN. It is evidence against a simpler mistake: humans do not walk through the world with one scoreboard labeled CASH. Material incentives matter, but so can identity, norms and what an action means inside a relationship.

THE TRUST PROBLEM

Trust is one of those words that becomes less precise the longer you stare at it. I trust my surgeon. I trust my friend. I trust the bridge. I trust that my child will eventually tell me what happened. Those sentences do not describe the same mechanism.

For this book, I care about a narrower piece: what trust does to uncertainty between people. Two people never have direct access to each other's future behavior. We infer. We reveal information. We make promises. We watch what happens. Trust changes how much uncertainty we can tolerate while continuing to act together.

That is why I became fascinated by speed. In sales, you can feel an interaction moving. A customer asks a hard question and gives you the real objection. Good. Now both people are working on the same problem. Another customer smiles, says everything sounds great, and hides the actual reason they will never buy. The conversation can look pleasant while going nowhere.

Calling that trust velocity is tempting. It sounds scientific. That is exactly why we should not use the phrase casually. Velocity has units. Distance divided by time. If we cannot define what is moving, in what direction, across what scale, measured by whom, then velocity is a metaphor wearing a lab coat.

So define the problem before naming the number. Suppose two people begin with different private models of a decision. We can measure how long it takes before the relevant differences are accurately represented in a shared record. We can measure how many turns are required before each person can state the other's concern. We can measure how quickly hidden information appears. We can measure whether the resulting action predicts what both parties said they wanted.

Now trust becomes experimentally useful. Manipulate whether disclosure is socially safe. Give one group a history showing that admitting uncertainty is rewarded. Give another a history showing that uncertainty reduces standing or membership. Then introduce the same hidden objection. Does it surface earlier? Does the group reach an accurate shared model faster?

Notice what we are not measuring. Agreement. Two people can understand each other perfectly and still disagree. In fact, forcing agreement can destroy the measurement by teaching people to hide the disagreement.

Trust, in this narrow sense, may be what allows humans to move through uncertainty created by other humans without requiring certainty first. Secure belonging may be one ingredient because it lowers the cost of revealing information that could create friction. But competence, honesty, incentives and past reliability obviously matter too.

The equation is not ready. Good. We have something better than a slogan: a measurement problem.

We have also reached the point where the book needs to come back down to earth. Hospitals, rocket boosters and factories are useful because the stakes

make the machinery visible. Most of us encounter the same uncertainty somewhere quieter: across a bed, at a dinner table, in the few seconds after somebody we love looks at someone else.

PART IV

DO YOU STILL CHOOSE ME?

LOVE YOU FOREVER

Robert Munsch's Love You Forever looks, at first glance, like an extremely simple children's book. A mother holds her baby. The child grows. The relationship changes. The mother ages. Eventually care moves in the other direction. Millions of readers encounter it as a story about a parent's love surviving time.

The origin makes the simplicity heavier. Munsch has written that he and his wife had two babies born dead, and that the story began as a song for them. For a long time, he could not sing it without crying. His regular publisher did not want the eventual book, so he took it elsewhere. On his official site, Munsch says the book has sold about fifteen million copies. A private expression of loss became something strangers used to talk about permanence.

The book is not a scientific study. Its popularity does not prove that humans possess a hidden membership variable. It gives us language for the thing we are trying to measure.

A child changes constantly. The infant who depends on you becomes the toddler who screams no, the teenager who closes the door, the adult who leaves, the person who builds a life you did not design. If love requires sameness, parenting is a catastrophic business model.

What many people seem to hear in the story is a promise that survives those state changes. Your behavior can alter what happens between us without erasing the deeper fact that you remain part of my world.

That promise is not the same as unlimited access. This matters enormously. Secure belonging does not mean a parent must accept abuse, fund addiction, tolerate violence, ignore boundaries or prevent an adult child from leaving. It does not mean the child owes the parent closeness. Love can survive a locked door.

This is one place ordinary language is better than our equations. I can love you and not trust you. I can trust your competence without loving you. I can want you in my future and still refuse to be in the same room today. The variables overlap without collapsing into one another.

The measurable question is not whether a person has unconditional love in some cosmic sense. It is whether the person expects the relationship to survive specific kinds of change. Disagreement. Failure. Distance. A new partner. A new sibling. A different belief. A boundary.

That expectation may be what secure belonging feels like from the inside: this event can change us without automatically ending us.

The strange beauty of the Munsch story is that the promise does not stop with the original relationship. Care moves forward. A person who was held becomes a person who holds. Love is finite in attention and still capable of propagation.

That may be the most hopeful form of abundance in this book. Not infinite time. Not infinite resources. A pattern that can be given away without disappearing from the person who taught it.
